What are Collective Coordinates?

- If N identical point particles reside in a region Ω at positions $\boldsymbol{r}_1$ ... $\boldsymbol{r}_N$, subject to periodic boundary conditions, the collective density variables $\rho(\boldsymbol{k})$ are defined thus:

$$\rho(\boldsymbol{k}) = \sum_{j=1}^{N} \exp(i\boldsymbol{k} \bullet \boldsymbol{r}_j)$$

- The applicable wave vectors have components:

$$\boldsymbol{k}_\gamma = \frac{2\pi \boldsymbol{n}_\gamma}{\boldsymbol{L}_\gamma} \qquad (\boldsymbol{n}_\gamma = 0, \pm 1, \pm 2, ... \gamma = \boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z})$$

- It is more convenient to work with the real quantities C(k)

$$\boldsymbol{C}(\boldsymbol{k}) = \sum_{j=1}^{N-1} \sum_{l=j+1}^{N} \cos[\boldsymbol{k} \bullet (\boldsymbol{r}_j - \boldsymbol{r}_l)]$$

$$-\frac{1}{2} \boldsymbol{N} \leq \boldsymbol{C}(\boldsymbol{k}) \leq \frac{1}{2} \boldsymbol{N}(\boldsymbol{N} - 1) \qquad (\boldsymbol{k} \neq 0)$$
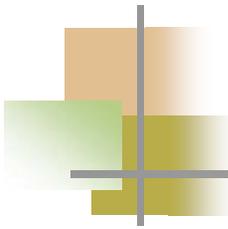

Collective Coordinates in the Literature

- Description of independent plasma oscillations resulting from long-range Coulomb interactions between electrons in metals

- Derivation of self-consistent integral equations for pair correlation functions in classical fluids

- Obtaining corrections to the random phase approximations for the electron gas

- Illustrating that large-scale density variations in superfluid ^{4}He are long-wavelength phonons
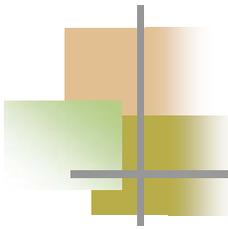

Why Study Collective Coordinates?

- Improve understanding of the non-trivial mathematical properties of collective density variables

- Means of generating classical ground states for particle systems
  - These configurations have applications in diverse fields, .e.g., materials science and ecology

- Means of obtaining initial conditions for gravitational studies in astrophysics
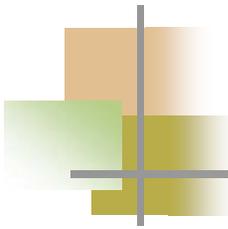

Method of Approach

- Our approach involves constraining C(k) parameters that lie in the wave vector set Q to values that are consistent with the minimization of the objective function Φ

$$\Phi(\boldsymbol{r}_1 ... \boldsymbol{r}_N) = \sum_{\boldsymbol{k} \in \boldsymbol{Q}} \boldsymbol{V}(\boldsymbol{k}) \big[\boldsymbol{C}(\boldsymbol{k}) - \boldsymbol{C}_0(\boldsymbol{k}) \big]^2 \qquad \boldsymbol{Q} : 0 \leq |\boldsymbol{k}| \leq \boldsymbol{K}$$

$$\boldsymbol{C}_0(\boldsymbol{k}) = -\boldsymbol{N}/2 + \boldsymbol{D}|\boldsymbol{k}|^{\alpha}$$

- Two Investigated Problems:
    - Generating classical ground states (D = 0)
   - Tailoring the structure factor S(k) (D ≠ 0) $\quad \boldsymbol{S}(\boldsymbol{k}) = 1 + \dfrac{2}{\boldsymbol{N}} \boldsymbol{C}(\boldsymbol{k})$

- We utilize the MINOP optimization technique in order to achieve sets of $\boldsymbol{r}_1 .... \boldsymbol{r}_N$ for which $\Phi = 0$.

The MINOP Algorithm[†]

- The algorithm minimizes a real-valued function of any number of variables based on user-provided first derivative and function information

- It applies a dogleg strategy which uses a gradient direction when one is far, a quasi-Newton direction when one is close, and a linear combination of the two when at intermediate distances from a solution

Tracking of the potential energy during an application of the **MINOP** algorithm to the structure factor tailoring problem.

Generating Classical Ground States

- As the number of constrained wave vectors is increased, the investigation distinguishes structural regimes as the number of wave vectors is increased
    - In one and two dimensions, three qualitatively distinct regimes are observed – disordered, intermediate, and crystalline regimes
    - In three dimensions, two distinct regimes emerge – disordered and crystalline regimes
- The choice of pair potential can lead to pair correlation functions that exhibit an effective hard core and thus, signal the formation of a hard-disk like equilibrium fluid
- Particle patterns that are hyperuniform in nature are generated. This supports the notion that structural glasses can be hyperuniform as the temperature T $\rightarrow$ 0.

Tailoring the *S(k)* Behavior

- We generate multi-particle configurations for which $S(k) \propto |k|^\alpha$, $|k| \leq K$, and $\alpha = 1, 2, 4, 6, 8,$ and 10.
  - The case $\alpha = 1$ is relevant for the Harrison-Zeldovich model of the early universe
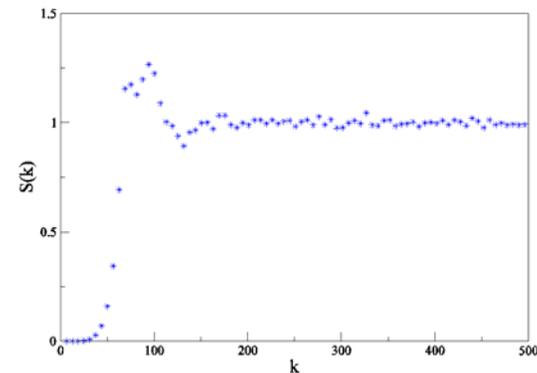

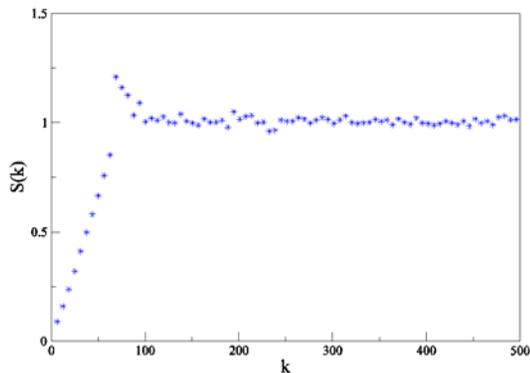

Tailored *S(k)* behavior for the Harrison-Zeldovich spectrum (left panel) and the k^6 spectrum (right panel).

- The corresponding real space particle patterns show decreasing clustering for increasing α
