

# Transfer Reactions on Argon Isotopes

Juan Manfredi SSGF Annual Review

June 22, 2017

# How can we test this picture?

- One answer: Spectroscopic Factors (SF)  $SF = \int d\vec{p} |\langle \Psi^{N-1} | a_{\vec{p}} | \Psi^N \rangle|^2$ 
  - SFs are a way to quantize the occupancy of a given single particle orbital  $0 \leq SF \leq 2j+1$

Less single-particle like (strong influence of nucleon-nucleon correlations)

 Can be interpreted as probability of finding core state N-1 within a composite state N when removing a nucleon in state p

U.S. Department of Energy Office of Science National Science Foundation Michigan State University More single-particle like (mean field is a good approximation)

• Example: SF( $f_{7/2}$ , <sup>41</sup>Ca g.s.) = 1.01 ± 0.06

#### Nuclear reactions can be used to extract SF's For example, consider a transfer reaction

- Nucleon(s) transferred to/from a projectile from/to a target
- In this case, consider A(p,d)A-1 in inverse kinematics

U.S. Department of Energy Office of Science National Science Foundation Michigan State University

Lee, PhD Thesis, Michigan State University 2010.

Neutron

transfer

#### Transfer Reactions To Study Nuclear Structure

- SF's are NOT observables...but can be *extracted* from experimental data via comparison to theory
- Transfer reactions have been successfully used to extract SF's for decades
  - Advent of radioactive ion beams opens up new sections of nuclear chart for exploration

U.S. Department of Energy Office of Science National Science Foundation Michigan State University MICHIGAN STATE

#### Extracting SFs

 Calculations tell us shape of angular distribution for transfer reaction to a given state with SF = 1

J. Manfredi, SSGF Annual Review

#### Transfer vs. Knockout

- Different reaction probes of SF *should* be consistent (nuclear structure is invariant)
- **Reduction factor**: compares experimental SF with shell model prediction

 Energy dependence of optical potential?
 Reaction mechanism energy dependent? Techniques/approximations unreliable at extremes of asymmetry, beam energy, cross section? Many body effects?

#### National Superconducting Cyclotron Laboratory (NSCL)

- Coupled Cyclotron Facility at the NSCL (on the campus of Michigan State University)
  - K500 and K1200 cyclotrons accelerate stable isotopes (from <sup>16</sup>O to <sup>238</sup>U) up to half the speed of light
  - Smash stable beam into Be target: fragmentation produces a wide variety of nuclei, some of which are exotic
  - A1900 Fragment Separator selects particular isotopes of interest, which are delivered to experimental areas

#### For this experiment

**Primary beams:** <sup>36</sup>Ar, <sup>48</sup>Ca Secondary beams: <sup>34</sup>Ar, <sup>46</sup>Ar

Michigan State University

FRIB

Measuring complete kinematics of <sup>34,46</sup>Ar(p,d) at 70 MeV/u

UN

 $\mathbf{v}$ 

R S

## Microchannel plates: MCPs

- MCPs are each calibrated using brass mask
- With calibrations, we can get beam position at each MCP, and therefore beam position at target

#### **S800 Spectrometer**

 To calibrate, account for dependence of TOF and ΔE on focal plane coordinates (CRDC positions/angles) <sup>33</sup>Ar

#### High Resolution Array: HiRA

- Modular array of Si + CsI charged particle detectors
- Measures energy, position information
- Energy loss in a "thin" detector vs. a "thick detector" yields particle identification (PID)

#### Conclusions

- Spectroscopic factors are an important tool in studying nuclear structure
- Nuclear reactions can be used to probe nuclear structure via extraction of spectroscopic factors
  - Discrepancy between transfer and knockout reactions
- High energy transfer reactions on proton-rich (<sup>34</sup>Ar) and neutron-rich (<sup>46</sup>Ar) argon isotopes were measured at the NSCL
- Next step: perform theoretical calculations, compare to data, and extract spectroscopic factors

#### Bethe Bloch Equation

$$-\frac{dE}{dx} = K z^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \beta^2 \gamma^2 T_{max}}{I^2} - \beta^2 - \frac{\delta(\beta\gamma)}{2}\right]$$

$$\beta \gamma = \frac{p}{E} \frac{E}{m} = \frac{p}{m}$$

A : atomic mass of absorber

$$\frac{K}{A} = 4\pi N_A r_e^2 m_e c^2 / A = 0.307075 \text{ MeV g}^{-1} \text{cm}^2$$
, for A = 1g mol<sup>-1</sup>

z: atomic number of incident particle

Z: atomic number of absorber

I : characteristic ionization constant, material dependent T<sup>max</sup>: max. energy transfer (see previous slide)

 $\delta$  ( $\beta\gamma$ ): density effect correction to ionization energy loss

![](_page_28_Picture_8.jpeg)

#### Deriving SF relation

- Fermi's golden rule
- DWBA Approximations:

Approximations: one step direct process, reaction weak enough to use 1<sup>st</sup> order perturbation theory, adiabatic approximation (deuteron breakup), distorted waves

• Assuming single particle states...

$$\frac{d\sigma}{d\Omega} = \frac{(2I_b + 1)(2I_B + 1)}{2\pi^2\hbar^4} \mu_i \mu_f \frac{k_f}{k_i} |T_{if}|^2$$

$$\left(\frac{d\sigma}{d\Omega}\right)_{\exp}^{\ell j} = S_{\ell j} \left(\frac{d\sigma}{d\Omega}\right)_{\rm DWBA}^{\ell j}.$$

![](_page_29_Picture_7.jpeg)

![](_page_29_Picture_10.jpeg)

![](_page_29_Picture_11.jpeg)

## Evaluation of transfer theory

- Nunes, et al claim transfer data corroborates knockout data
- Quantified errors in reaction theory from optical potential by performing exact three-body Faddeev calculation
- But...large (20%) divergence between Faddeev and ADWA results
- PRC 83, 034610
